

The Heart in Hypertension (International Boehringer Mannheim Symposia)

Hypertensive heart disease is one of the most frequent diseases in man. It is estimated that there are six to eight million hypertensive patients in the Federal Republic of Germany today. This corresponds with an incidence of 10%-15% in the whole population. Approximately between three and four million show organic cardiac manifestations of hypertension. Of all deaths occurring before the age of 65, 30%-40% are attributable to hypertension, and the total mortality from hypertension is about 20%-25%. Recent epidemiological and clinical studies have revealed similar figures for other countries, such as the United States and Japan. Hypertensive hypertrophy and cardiac failure are found to be many times more frequent than cardiac hypertrophy and failure of any other origin. Despite the apparent clinical and social importance of the biological system blood pressure and the heart, data on cardiac performance, on systemic and coronary haemodynamics and on the morphological, biochemical and contractile properties of ventricular heart muscle in both experimental and clinical hypertension are rare. This is the reason and stimulus for having organized this symposium, which is the first one concerning this topic.
